Lesbian, Gay and Bisexual Patients: The Issues for General Practice

Author: Odhrán Allen
Disclaimer and Waiver of Liability

Whilst every effort has been made by the Quality in Practice Committee to ensure the accuracy of the information and material contained in this document, errors or omissions may occur in the content.

This guidance represents the view of the ICGP which was arrived at after careful consideration of the evidence available.

This guide does not however override the individual responsibility of healthcare professionals to make decisions appropriate to the circumstances of individual patients in consultation with the patient and/or guardian or carer.

Evidence-Based Medicine

Evidence-based medicine is the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients.

In this document you will see that evidence and recommendations are graded according to levels of evidence (Level 1 – 5) and grades of recommendations (Grades A-C) respectively. This grading system is an adaptation of the revised Oxford Centre 2011 Levels of Evidence.

Levels of evidence

Level 1: Evidence obtained from systematic review of randomised trials

Level 2: Evidence obtained from at least one randomised trial

Level 3: Evidence obtained from at least one non-randomised controlled cohort/follow-up study

Level 4: Evidence obtained from at least one case-series, case-control or historically controlled study

Level 5: Evidence obtained from mechanism-based reasoning

Grades of recommendations

A Requires at least one randomised controlled trial as part of a body of literature of overall good quality and consistency addressing the specific recommendation. (Evidence levels 1, 2)

B Requires the availability of well-conducted clinical studies but no randomised clinical trials on the topic of recommendation. (Evidence levels 3, 4).

C Requires evidence obtained from expert committee reports or opinions and/or clinical experience of respected authorities. Indicates an absence of directly applicable clinical studies of good quality. (Evidence level 5).

1 Introduction

1.1 Background

This guide is written for general practitioners to advance their understanding of what they need to know when treating lesbian, gay or bisexual (LGB) people in the primary care setting. In recent years, a number of national policies and reports have highlighted the need for LGB people’s health needs to be considered by health professionals and for health care providers to be inclusive of this patient group in their practice.

A recent Irish study found that 45% of participants actively seek out LGB-friendly healthcare professionals because of bad experiences they had in the past and 28% admitted to hiding the fact that they were gay for fear of a negative response from professionals. This guide has been developed to support general practitioners in their efforts to provide an appropriate and accessible primary care service to LGB people in their care.

1.2 Aims of the Document

This guide aims to address the most common questions and information gaps that general practitioners may have in relation to providing primary care to LGB people. To achieve this it covers:

- Sexual orientation concepts and language
- A review of LGB health issues
- Good practice in service provision to LGB patients

This guide also contains a glossary of terms, a services directory, and a list of resources for general practitioners and references.

1.3 Key Points & Recommendations

For the most part LGB people face the same health issues as heterosexual men and women. However, there are a number of specific health issues which general practitioners should be aware of in relation to these patients particularly in the areas of mental health, sexual health and general health and screening. A good understanding of these issues is the foundation of providing an inclusive service to LGB patients.

This guide makes five recommendations for good practice with LGB patients:

- Stay informed on LGB health issues
- Don’t assume patients are heterosexual
- Acknowledge when patients disclose they are lesbian, gay or bisexual
- Take a gay-affirmative approach and challenge bias
- Demonstrate that your practice is LGB-friendly

GLEN would like to acknowledge the Irish College of General Practitioners’ commitment to promoting the highest standards of primary care for all patients, including LGB patients, and would like to thank Dr. Margaret O’ Riordan, Dr. Maria O’ Mahony and the Quality in Practice Committee for their support in developing this quick reference guide.

2 Lesbian, Gay & Bisexual Patients: The Issues for General Practice

In order to support general practitioners to respond appropriately and effectively to lesbian, gay and bisexual patients, this section will clarify terms and concepts relevant to lesbian, gay and bisexual people and their sexual orientation.

2.1 Sexual Orientation – concepts and language use

Sexual Orientation

LGB is an acronym used throughout this document to refer to lesbian, gay and bisexual people. Sexual orientation is one of the four components of sexuality and is distinguished by an emotional, romantic, sexual or affectionate attraction to individuals of a particular sex. The three other components of sexuality are biological sex (whether we are born as a male or female), gender identity (the psychological sense of being male or female) and social gender role (the extent to which people conform to what is regarded in our society as feminine and masculine behaviour).

Three sexual orientations are commonly recognised: heterosexual (attraction to individuals of the opposite sex), homosexual (attraction to individuals of one’s own sex) and bisexual (attraction to members of both sexes). Many LGB people do not like the use of the term homosexual to describe their sexual orientation because of negative historical associations with this word. Most people prefer the word gay if they are male and lesbian if they are female.

Sexual orientation is different from sexual behaviour because it refers to feelings and individuals’ views about who they consider themselves to be. Sexual behaviour is simply how people behave in a sexual situation. Individuals may or may not express their sexual orientation in their behaviours. Being lesbian, gay or bisexual is not a preference and is not chosen. It is integral to a person’s life and their identity rather than being a lifestyle. Our sexual orientation reflects a complexity of factors that determine who we are sexually attracted to and who we fall in love with.

Coming Out

Disclosure that one is lesbian, gay or bisexual is often referred to as ‘coming out’. However, there is more to coming out than disclosure of one’s sexual orientation. Coming out is an important and affirmative developmental process in the lives of LGB people with distinct phases. It first involves accepting one’s sexual orientation and then choosing to share this with others as well as developing a positive sexual identity. While some people have negative experiences the majority of LGB people experience great relief when they come out and are met with support and acceptance from family, friends and colleagues. This is reflected in more positive social attitudes. However, coming out can be a time of heightened stress which may result in LGB people presenting to primary care and mental health services.

Inclusive Practice

Inclusive practice applies to all forms of diversity, including sexual orientation and it means that general practitioners:

- Recognise diversity among their patient population and respect this diversity
- Understand the issues facing diverse patient groups (such as LGB patients) and are able to respond to their specific health needs
- Provide an accessible and appropriate service within their scope of practice and refer patients on to specialist or other services where necessary

Since the declassification of homosexuality as a mental health disorder, health professionals have played a leading role in reducing the stigma and prejudice created by the pathologisation of homosexuality. This has largely been achieved through the establishment of a more evidence-
based view of human sexuality, challenging the unscientific basis of anti-gay bias and by establishing standards for inclusive practice such as this guide.

**Civil Partnership**

The recent passing of the Civil Partnership and Certain Rights and Obligations of Cohabitants Act 2010\(^{12}\) has introduced the new civil status of Civil Partner which confers broadly similar legal status as a married heterosexual couple. The Equality legislation has now been amended replacing marital status with the new category of civil status which prohibits discrimination on the grounds of being married, in a civil partnership or being single. Therefore, GPs should treat a same-sex civil partnered couple in the same way as they would a married heterosexual couple in the context of their legal rights and entitlements. Unless an LGB patient indicates otherwise, practitioners should recognise their same-sex partners as next-of-kin and involve them as appropriate in the service being provided.

The enactment of the civil partnership legislation provides same-sex couples with many of the same entitlements and will be subject to many of the same legally enforceable duties and obligations as parties to a civil marriage. The provisions of the Civil Partnership Act include protections and obligations across areas such as protection of the couple's shared home, next of kin, residential tenancies, pensions, taxation, maintenance, social welfare, succession, immigration, domestic violence and refugee law.

Despite the very significant progress civil partnerships brings, this legislation does not recognise or protect children in same-sex headed families. This leads to varying levels of uncertainty and vulnerability for gay and lesbian parents and their families. Some LGB people may have had their children in the context of a heterosexual relationship while others have children outside the context of heterosexual relationships and marriage (e.g. fostering, adoption and assisted human reproduction).\(^{13}\) Unlike heterosexual parents, LGB parents can be subject to prejudice and negative assumptions about their parenting ability because of their sexual orientation.\(^{14}\) The Irish Association of Social Workers review of international research comparing the development of children with gay and lesbian parents and children with heterosexual parents found no significant developmental differences between the two groups of children in their intelligence, psychological adjustment, social adjustment, popularity with friends, development of social sex role identity or development of sexual orientation.\(^{15}\)
2.2 Review of lesbian, gay and bisexual health issues

For the most part LGB people face the same health issues as heterosexual men and women. However, there are a number of specific health issues which general practitioners should be aware of in relation to these patients. A good understanding of these issues is the foundation of providing an inclusive service to LGB patients. The issues can be grouped into three general areas:

- Mental health
- Sexual health
- General health and screening

Mental Health

A large body of published empirical research clearly refutes the notion that homosexuality per se is indicative of or correlated with psychopathology. However, given the stresses created by stigma, inequality and harassment, LGB people are at a heightened risk of psychological distress related to these experiences. \(^{16,17,18,19,20}\) This is often referred to as minority stress, a term used to describe the mental health consequences of stigmatisation, social exclusion, discrimination and harassment of minority groups such as the LGB population. This concept is particularly useful when explaining mental health issues related to being LGB because it is centred on an understanding that alienation from social structures, norms and institutions can create psychological distress and increase the risk of suicide. \(^{21,22}\)

While it is not the case that all LGB people are at elevated risk of poor mental health as a consequence of minority stress, research evidence consistently indicates elevated levels of suicidality among the LGB population and elevated levels of mental health risk factors, such as depression, isolation and substance misuse, which increase the likelihood of suicidal behaviour. The findings of this research have been consistently interpreted as resulting from the aforementioned minority stress.

Although social attitudes towards lesbian, gay and bisexual people have changed markedly in recent years, nevertheless LGB people can still experience discrimination, exclusion and harassment, and young people in particular may be affected by homophobic bullying, resulting in psychological distress and feelings of isolation. This is particularly true for people becoming aware of their lesbian, gay or bisexual orientation as a young person, which is increasingly common. \(^{6,7,23,24,25}\) Depending on their families and where they live, LGB people may have to struggle against prejudice and misinformation about their sexual orientation and often fear being rejected by family and friends if they come out. \(^{6,7}\) This can be compounded by rural isolation for those living outside of urban areas.

Research has also found that coming out and acceptance of one’s LGB sexual orientation is strongly related to good psychological adjustment, i.e. the more positive one’s lesbian, gay or bisexual identity is, the better one’s mental health and the higher one’s self-esteem. \(^{7,26}\)

General practitioners should provide these patients with the opportunity to discuss experiences which have impacted on their mental health and where appropriate screen LGB patients for mental health and suicide risk factors such as psychological distress, depression, anxiety, substance misuse and lack of social support. Referral to mental health services and other support services, such as counselling and psychotherapy, should be considered where appropriate. Patients can also benefit from referral to LGB organisations (See Appendix).

The Supporting LGBT Lives Report

The Supporting LGBT Lives study\(^6\) examined LGBT mental health risk and resilience for the first time in an Irish context. A key finding of this study, in which 1,110 people participated, was that LGBT people, and young people in particular, are at risk of suicidal behaviour related to difficulties before and after coming out to their family and in school. Below are the key mental health findings of the study.
Findings on ‘Coming Out’
- 12 years of age = the most common age to realise one’s LGBT identity
- 17 years of age = the most common age to first disclose one’s LGBT identity to anyone
- 5 years = the most common number of years that young LGBT people conceal their identity from others. This 5 year period coincides with puberty, school and a critical period of social, emotion and vocational development.
- The period prior to coming out was particularly stressful because of fear of rejection (from parents in particular) and because of isolation
- The majority came out to a friend or another trusted individual before coming out to their family. Friends and family, but parents in particular, have a crucial role to play in supporting LGBT people as they come out and this support can act as a protective buffer against specific stresses LGBT young people may encounter such as homophobic bullying in school.

Findings on Mental Health and Suicidality
- 27% had self-harmed and 85% of these did so more than once
- 16 years was the average age of first self-harming
- 40% of females and 20% of males had self-harmed
- 18% had attempted suicide and 85% saw their first attempt as related to stresses associated with their LGBT identity (e.g. fear of rejection by family or friends)
- 17.5 years was the average age of first suicide attempt
- 24% of females and 15% of males attempted suicide at least once
- Over a third of those aged 25 years and under had thought seriously about ending their lives within the past year and over 50% had done so at some time
- The 3 most common LGBT-specific stresses identified were:
  - fear of rejection when considering coming out;
  - negative school experiences; and
  - experiences of harassment and victimisation

**Sexual Health**

As noted above, most LGB patients present to general practitioners with the usual range of health issues seen in general practice and routine recommendations apply. However, there are particular sexual health issues that should be considered by general practitioners when assessing these patients. Provision of screening services for sexually-transmitted infections (STI) for all patients at primary care level is under-developed in Ireland. This, coupled with some patients’ reluctance to disclose their sexual orientation to general practitioners and/or discuss their sexual behaviour, may result in inadequate sexual health screening and treatment. As there are some differences between sexual health issues for gay and bisexual men and lesbian and bisexual women, this section will discuss these separately.
Gay and Bisexual Men's Sexual Health

In discussing gay and bisexual men's sexual health it is important to consider other men who have sex with men but who do not identify as gay or bisexual. MSM is an epidemiological term to encompass all men in this group.\(^{44,45}\) STI screening and HIV prevention remains central to primary health care for MSM.\(^{40,44,46,47,48}\)

In recent years there has been a marked increase in the level of HIV and sexually transmitted infection (STI) diagnoses in the MSM group.\(^{49}\) The sharp increase in HIV diagnosis rates comes at a time when there have been marked decreases in diagnosis rates for heterosexual transmission and transmission through injecting drug use (IDU). In addition there have been outbreaks of syphilis concentrated within the MSM population.\(^{50}\) Some of the key statistics and emerging trends are:

- 127% increase in MSM HIV diagnoses between 2005 and 2011
- Highest proportion of new HIV diagnoses in 2011 were among MSM (43%)
- The median age of newly diagnosed MSM patients is declining. It was 33 years in 2011
- 72% of cases in 2011 were white MSM
- 147% increase in MSM syphilis diagnoses between 2005 and 2011
- MSM accounted for 80% of early case syphilis diagnoses in 2011

There are several direct linkages between patients accessing sexual health services and HIV and STI infection rates. It is in the early stages of HIV that the condition is most highly transmissible.\(^{51}\) This is because the viral load is very high in the first few months. If the person is unaware of their status then this increases the potential for further transmission of the condition. Early detection of infection at a time of high HIV infectivity will be more advantageous to lowering HIV incidence than later diagnosis and more advantageous in the care and treatment of people living with HIV.\(^{52}\) Recent research using phylogenetic technology highlighted the occurrence of transmission clusters of new HIV cases, mainly amongst younger men, who have been recently infected and who were unaware of their HIV positive status.\(^{53}\) Irish data also suggest that re-infection of syphilis is common among MSM and in particular, among those who are HIV positive.\(^{50}\)

General practitioners should assess the STI-related risks for all male patients, including a routine inquiry about the gender(s) of sexual partners. STI-risk level is influenced by factors including relationship status, HIV status, number of sexual partners and recreational drug use. MSM at higher risk should be screened for STIs including HIV, syphilis, gonorrhoea and chlamydia at least on an annual basis (even in the absence of any symptoms) and immunisation against hepatitis A and B should also be advised.\(^{51}\) Increasing both the numbers and frequency of MSM accessing sexual health services is a critical part of HIV/STI prevention, both for the individual patients and for reducing onward transmission rates.\(^{58}\)
HIV-related sexual risk-taking among MSM is more likely when excessive alcohol consumption co-occurs with sexual activity.\textsuperscript{34,55,56} Recent research indicates that patients presenting to GPs with symptoms of early-stage HIV infection (e.g. sore throat, fever and rash within two to six weeks of infection) are often misdiagnosed.\textsuperscript{57} It should be noted that gay and bisexual men do not encounter more sexual dysfunction than heterosexual men.\textsuperscript{37}

GPs have a role in motivating patients to reduce risky sexual behaviours by discussing recent increases in STIs among MSM, explaining the transmission synergy between HIV and other STIs and helping them understand how STIs are contracted.\textsuperscript{60,64} Sexual health literature for gay and bisexual men is available from the various LGB organisations (See Appendix 2).

**Lesbian and Bisexual Women’s Sexual and Gynaecological Health**

Lesbian and bisexual women have some specific sexual health needs. Lesbian and bisexual women have been perceived as a low risk group by both lesbians and bisexual women and healthcare providers. As a result, they can run the risk of being largely over-looked in terms of sexually transmitted infections and cervical cytology screening initiatives.\textsuperscript{38}

While many lesbian and bisexual women have children, they have significantly fewer pregnancies, miscarriages and abortions than heterosexual women, as well as a lower use of birth control pills. These factors place lesbian women at higher risk of developing ovarian cancer.\textsuperscript{59,60,61} Research also indicates that lesbians are less likely than heterosexual women to avail of or be referred for cervical smear tests and mammography or to examine their own breasts.\textsuperscript{59,62} General practitioners should encourage lesbian and bisexual women to have regular cervical smear tests and carry out regular breast self-examination.

General practitioners may incorrectly assume that lesbian and bisexual women are at low risk for cervical dysplasia and need less frequent cervical smears than heterosexual women.\textsuperscript{63,64,65} Human papillomavirus-associated squamous intraepithelial lesions have occurred in lesbians who have never had sex with men.\textsuperscript{66} Recommendations for cervical cancer screening in lesbian and bisexual women, regardless of their sexual history with men, should therefore not differ from screening recommendations for women in general.\textsuperscript{64,67,68} It should be noted that lesbian and bisexual women encounter no more sexual dysfunction than heterosexual women.\textsuperscript{37}

STI screening is an important component of primary health care for lesbian and bisexual women.\textsuperscript{51,69} Lesbian and bisexual women are less likely than heterosexual women to be tested regularly for STIs.\textsuperscript{69}

Lesbian and bisexual women who believe themselves to be in a low risk group for HIV and STIs are less likely to practise safer sex than heterosexual women with partners from higher prevalence groups.\textsuperscript{70} A significant number of lesbian and bisexual women have a history of having previous or current sexual contact with men.\textsuperscript{71} This demonstrates that a woman’s sexual identity is not always an accurate predictor of her sexual behaviour or risk level, with women who define themselves as lesbian sometimes engaging in high-risk sexual contact with men. In addition, many STIs can be contracted through other sexual practices more common to lesbian and bisexual women such as oral sex and the use of sex toys. For this reason lesbian and bisexual women should be offered full STI screening.\textsuperscript{58}

Educating lesbian and bisexual women about the risks of STIs and dispelling the perception that the transmission of STIs between women is negligible will help patients make more informed decisions. General practitioners should encourage sexually active lesbian and bisexual women to be screened for STIs in the same way as with heterosexual female patients.

**Taking a Sexual History**

When patients present with symptoms related to sexual activity they may feel embarrassed. Gay men may find it difficult to discuss certain sexual practices such as anal sex\textsuperscript{35} while lesbian women report finding it harder to talk to a male doctor.\textsuperscript{71,72} General practitioners can help alleviate this
discomfort by taking a patient’s sexual history in a sensitive, non-judgemental and comprehensive manner; by emphasising that the discussion is routine and confidential; and by underscoring the importance of needing to know the patient’s sexual practices in order to determine risk, appropriate screening and treatment options for optimal care.

Each doctor develops their own style of taking a sexual history. There are many helpful publications to assist in developing this skill such as Tomlinson or Lloyd and Bor. It is also worth considering developing a practice guide based on the template from Curtis et al. As a GP, the focus is on sexual behaviour and the risks associated with this. Below are suggested questions for taking a sexual history from patients.

**TAKING A SEXUAL HISTORY**

**Ask Men and Women:**
- Are you sexually active?
- Do you have sex with men, women or both?
- How many partners have you had in the past six months?
- What sexual acts do you engage in? (check for oral, vaginal and anal sex)
- Are you aware of the times when you should use condoms/dental dam?
- What do you do to protect yourself from STI and HIV infection?
- Have you any concerns about sexual risks you may have taken?
- Do you have any questions about STIs?
- Do you have any questions or concerns about sex?

**Additional Questions for Women:**
- Have you ever been pregnant?
- Is there any chance you might be pregnant?
- Do you have any questions or concerns about your gynaecological health?

**General Health & Screening**

Most LGB people will present to GPs with the usual range of health issues seen in general practice and routine health recommendations will apply. However, research on health-related behaviours among this group has shown elevated levels of smoking, alcohol consumption and recreational drug use when compared to their heterosexual peers. There is also some evidence that lesbian women may be at more risk of obesity than their heterosexual peers. Little data exists to describe why these elevated levels exist but it’s useful for general practitioners to be aware of these findings and to screen LGB patients for tobacco, alcohol and drug use and offer appropriate interventions. The following table summarises the research evidence on LGB health-related behaviours.

2.3 Good practice in service provision to lesbian, gay and bisexual patients

This section will describe the different ways that general practitioners can improve service provision to ensure that their practice is inclusive of the needs of LGB patients. Given that approximately 8 per cent of the population identify as LGB\(^6\) it follows that a similar percentage of patients attending a given general practice will also be LGB. A recent study of 1,110 LGB people in Ireland\(^6\) which examined amongst other things LGB people’s experience of using GP services, found that:

- 76.9% felt GPs need to have more knowledge and sensitivity to LGB issues
- GPs were only aware of respondents LGB identity in 44% of cases
- Only 40% felt respected as an LGB person by their GP
- 28% admitted to hiding the fact that they were gay for fear of a negative reaction

This indicates that a significant number of LGB respondents perceived their GP as not having the knowledge and understanding to provide a service appropriate to their needs. In addition to this, GPs typically presumed that their patients were heterosexual, leading to reluctance on the part of these patients to disclose their sexual orientation and associated health issues or concerns. Lesbian patients were more likely than gay men to report a history of difficulties with GPs, and in particular reported difficulties having their sexual and gynaecological health needs met. Below are five general guidelines to support GPs in providing a service to their LGB patients.

1 Stay informed on LGB health issues

While LGB people are as diverse and varied a group as heterosexual people, these patients can face a number of barriers to receiving quality health care, including:

- Doctors’ assumption that patients are heterosexual and/or their hesitancy to inquire about sexual orientation
- Doctors’ lack of understanding of LGB health issues
- LGB patients’ fear of negative reaction when disclosing their sexual orientation or previous experience of negative responses from practitioners
- LGB patients’ discomfort discussing their sexual behaviour

Being aware of the health needs of this patient group (see 2.2) and of the barriers they can face in having their health needs met is key to improving service provision to LGB patients. The Supporting LGBT Lives and Visible Lives research reports provide very useful information for practitioners and increasing research publication in peer review journals can also assist GPs in keeping informed on LGB health.

2 Don’t assume patients are heterosexual

Any person who uses your service may identify as gay, lesbian, or bisexual or have a history of relationships with members of the same sex. Such patients may or may not have come out. By asking open and inclusive questions when taking a patient’s medical history, you are demonstrating to LGB patients and those questioning their sexual orientation that they are welcome to disclose their sexual orientation to you or to discuss issues related to their sexual orientation that may be relevant to their health needs.

Be aware that you already have lesbian, gay and bisexual service users, even if you don’t know who they are. Use the terms lesbian, gay and bisexual instead of the term homosexual when talking to patients as most LGB people are more comfortable with this language and may associate the word homosexuality with pathologisation. Using open language and questions is a very good of demonstrating to patients that you are not assuming they are heterosexual.
The following are some examples:

### EXAMPLES OF INCLUSIVE QUESTIONS

<table>
<thead>
<tr>
<th>Say:</th>
<th>Instead of:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do you have a partner?</td>
<td>Are you married?</td>
</tr>
<tr>
<td>Are you in a relationship?</td>
<td>Do you have a girlfriend/boyfriend?</td>
</tr>
<tr>
<td>What is your partner's name?</td>
<td>What is your husband/wife's name?</td>
</tr>
</tbody>
</table>

A situation that may arise is that you think a patient is struggling to disclose their sexual orientation to you. In this instance, as with any sensitive matter, you can encourage them to disclose by providing them with reassurance and showing interest in understanding them. The following are some suggestions for how you may do this:

- Reassure the patient that all personal information disclosed is confidential and that you provide a non-judgemental service.
- Explain the importance for you as their general practitioner in understanding issues that are relevant to their health so that you can identify the appropriate treatment or supports that they may need.
- Enquire about relationships both current and past.
- Try asking indirectly. For example, “In my practice I see a lot of straight and gay people struggling with issues like relationships. Might this be relevant to you?”
- Try asking directly. For example, “Is your partner a man or a woman?” “Are you attracted to men, women or both?” “Have your past relationships been with men, women or both?”

If someone is hinting at an LGB issue, you could try asking something like "It sounds as if you are questioning your feelings/identity/orientation… has that been on your mind". For some patients, using language like ‘sexual orientation’ or ‘gay’ may be too threatening. The above question is an example of how you can hint at these without stating them explicitly. You can also explain to the patient the importance for you as their doctor of understanding issues that are relevant to their health so that you can identify the appropriate treatment or supports that they may need.

### 3 Acknowledge when patients disclose they are lesbian, gay or bisexual

Young LGB people in particular may be questioning their sexual orientation or seeking help in clarifying romantic feelings. Helping young people to feel safe and supported will facilitate their process of self-acceptance and coming out. Just as we know that talking with teens about sex does not increase their sexual behaviour, talking about sexual orientation does not make a teen homosexual or heterosexual.

Coming out is an important time in LGB people’s lives and asking LGB patients about their experience of coming out demonstrates your understanding that this is an important part of their lives. Clinically, it is potentially also a time of heightened mental health risk, particularly for younger LGB people.\(^{22,33,39}\) Ways of asking patients about coming out and related life experiences include:

- “Do any of your friends know you are lesbian/gay/bisexual?”
- “Have you come out to anyone in your family?”
- “How have things been for you since you came out?”
- “Have you had any negative experiences since coming out?”
- “Are there lesbian/gay/bisexual people you know that you can talk to? Are they supportive?”
- “Are there any issues you would like to discuss with me related to your sexual orientation?”

While these questions may be relevant to ask, LGB patients’ sexual orientation may not be relevant to their use of your service at a particular time. Also remember that some LGB patients may not have fully accepted their sexual orientation or may only be in the very initial stages of coming out. This should be dealt with sensitively by general practitioners. If a young person tells you he or she may be
or is lesbian, gay or bisexual, it is appropriate to respond in a positive and supportive way. Try to avoid the assumption that he or she is going through a phase or is too young to make such a declaration. Provide information that will support and reassure the young person and consider referring them to an LGB organisation for support.

4 Take a gay-affirmative approach and challenge bias

A gay-affirmative approach affirms a lesbian, gay or bisexual identity as an equally positive human experience and expression to heterosexual identity and is increasingly considered the preferred method to work in a culturally competent manner with this patient group.

While anti-gay bias is something that many GPs would not consider to be an issue in their own practice, it is important to acknowledge that where it does exist it results in LGB patients receiving sub-optimal care. Even the most subtle or indirect forms may have an adverse effect on the doctor-patient relationship and the person’s willingness to disclose relevant personal information and health concerns to their general practitioner. The characteristics of professional anti-gay bias are:

- Presuming patients are heterosexual
- Pathologising, stereotyping and stigmatising LGB patients
- Failing to empathise with or recognise LGB patients’ health concerns
- Failing to appreciate any non-heterosexual form of behaviour, identity, relationship, family or community
- Making unsolicited attempts to change a patient’s sexual orientation

Reparative therapy or any attempts to alter LGB patients’ sexual orientation should be avoided by general practitioners. All guidance and counselling offered to these patients should be person-centred and gay-affirmative.

General practitioners should also be mindful of bias when treating a child with same-sex parents. If you are seeing a child with same-sex parents, include both parents in the discussion. Health care may be compromised if one of the primary caregivers is excluded. LGB people may wish to be parents and lesbian women may intend future pregnancies and have concerns about their fertility. Questions about planning a family are an important part of their sexual health assessment. Biological parent and non-biological parent are the respective terms to describe the parent who did and didn’t conceive the child.

5 Demonstrate that your practice is LGB-friendly

There are a number of practical things you can do to demonstrate your openness to and inclusion of LGB people in your practice:

- Ensure all relevant paperwork, information leaflets and history taking questions use language which is inclusive of LGB people and their families. For example, on a registration form rather than asking for Marital Status ask for Civil Status.
- Consider displaying LGB leaflets and/or a poster in your waiting room e.g. leaflets from an LGB service, LGBT helpline poster or specific LGB information (available from your local LGB organisation – see appendix 3).
This practice values the dignity of all patients and does not discriminate on the basis of gender, marital status, family status, age, disability, race, nationality, sexual orientation, or religious belief.

**Inclusive Practice - Suggested Wording for Waiting Room Poster**

- Include LGB people in general health information, e.g. in sexual health leaflet for female patients include information for lesbian and bisexual women, such as the need for smear tests.
- Name LGB people in service ethos statement, e.g. that your service recognises and respects the diversity of patients based on age, gender, sexual orientation, etc.

The doctor-patient relationship is central to the quality of care provided and health outcomes achieved when treating all patients. These five recommendations address the different ways of communicating your openness, respect and understanding to LGB patients which will promote an optimum doctor-patient relationship between you and your LGB patients. By following these recommendations you can ensure you are providing an accessible and appropriate primary care service to LGB patients attending your practice.

APPENDIX 1:  Glossary of Key Terms

SEXUAL ORIENTATION is an enduring pattern of emotional, romantic, and/or sexual attractions to men, women, or both sexes. Sexual orientation also refers to a person's sense of identity based on those attractions, related behaviours, and membership of a community of others who share those attractions.

GAY A gay person is a man or woman who is romantically, sexually and/or emotionally attracted to people of the same sex. Most gay men prefer to be called gay rather than homosexual. Most gay women prefer to be identified as lesbian rather than gay or homosexual.

COMING OUT is the term used by lesbian, gay and bisexual people to describe their experience of self discovery, self-acceptance, openness and honesty about their sexual orientation and their decision to disclose, i.e. to share this with others when and how they choose.

LGBT is an acronym for lesbian, gay, bisexual and transgender.

TRANSGENDER is an umbrella term used to describe people whose gender identity (internal feeling of being male or female) and/or their outer gender expression, differs from that usually associated with their birth sex. Not everyone whose feelings, appearance or behaviour is gender-atypical will identify as a transgender person. Many transgender people live part-time or full-time in another gender. Transgender people can identify as transsexual, transvestite or another gender identity. See www.teni.ie for more information.

HOMOPHOBIA refers to fear of or prejudice and discrimination against lesbian, gay and bisexual people. It is also the dislike of same-sex attraction and love or the hatred of people who have those feelings. While homophobic comments or attitudes are often unintentional, they cause hurt and offence to LGB people.

INTERNALISED HOMOPHOBIA is the fear and dislike of one's sexual orientation that occurs in some lesbian, gay and bisexual people. Having been exposed to homophobia growing up, some LGB people internalise this stigmatisation of homosexuality resulting in feelings of fear, shame, guilt and low self-esteem. LGB people who experience internalised homophobia can overcome it by being supported to accept their sexual orientation and to build a positive LGB identity.
